MIREKU

SAMPLED INSTRUMENT · AMANORSAC STUDIO

Importing Yamaha Libraries

Turning your own **.X7L** and **.X8L** files into MIREKU instruments, from inside the plug-in. No studio round trip, nothing overwritten.

User manual · Version 1.0 · October 2026

AMANORSAC STUDIO

What this does

MIREKU reads a Yamaha library file, finds the sampled audio inside it, and writes each instrument out as a **.jmi** bundle in your library folder. When it finishes, the new instruments are in the browser and ready to play. You do not need to send anything to the studio.

It takes **.X7L** and **.X8L** files. Everything else is ignored by the file chooser.

> **Before you start.** Set your **library folder** first. That is where imported instruments are written, and the import will stop and tell you if it has not been set. The folder is shown on screen, directly above the button you are about to press — so you can always see where the files are going before anything starts.

The steps

1. Open any instrument page and choose the **SETTINGS** tab — the one between EQ and INFO.
2. Check the **LIBRARY FOLDER** path at the top of the page. If it is wrong or empty, press **BROWSE…** and pick the folder you want. Imported instruments land here.
3. Press **IMPORT LIBRARY…**
4. The file chooser opens in your **Downloads** folder and shows only **.X7L** and **.X8L** files. Pick **one, or as many as you like** — a batch is handled in a single run.
5. A progress window appears and tells you which file it is working on. A library is hundreds of megabytes and every sample is written to disk, so expect **minutes, not seconds**. You can carry on looking at the plug-in while it runs, and there is a **Cancel** button if you need it.
6. When it finishes you get a **summary**. Read it — it is the only place that tells you if a file was turned away. Close it and your new instruments are already in the browser; the library re-scans itself.

Reading the summary

One line per file you selected, then the totals. A line that succeeded names every instrument that came out of that file:

```
MKS20.X7L  ->  3 instrument(s): MKS20, MKS20_Soft, MKS20_Tines

1 of 1 file(s) imported, 3 instrument(s), 188 sample(s), 412.6 MB written.
```

A line that did not succeed says **not imported** and gives the reason. Nothing was written for that file.

Rules the importer follows

Nothing is ever overwritten	If an instrument name is already taken — on disk, or by something imported earlier in the same run — the new one gets a number: **MKS20_2**. Your existing bundles are never touched.
Cancelling keeps what it had	Press Cancel and whatever was already written stays. The summary says so. Nothing is half-written: an instrument is either complete or not there.
A refused file writes nothing	If a library is turned away, no part of it reaches your folder.
Everything is stamped with your name	Imported instruments carry **James Mireku** as the author.

When a file is turned away

There are three reasons, and each one tells you what to do about it.

Reason	What it means and what to do
The file is incomplete	*"… bytes are missing. Copy it again; nothing was written."* The transfer did not finish. This is the common one with large libraries sent over the internet — the download stopped early and the file on disk is a fragment. **Send or download it again**, then import it. The message tells you exactly how many bytes are short, so you can see at a glance whether you got half the file or almost all of it.
No sampled audio in it	*"it holds patch parameters but no sampled audio…"* The file is real and readable, but it only contains synth patch settings — knob positions, not recordings. There is nothing to convert. Sounds like these have to be **sampled off the hardware** first.
Not a library this can read	The file is damaged, or it is not a Yamaha library at all despite the extension. Check you picked the right file.

> **If it is taking a very long time.** That is usually normal — the time is spent writing samples, so a big library on a slow disk is genuinely slow. The progress window names the file it is on, so you can tell it is moving. If you need the machine back, Cancel is safe.

After the import

The new instruments appear in the browser straight away. They sit in the same library folder as everything else, so they are mixed in with your existing instruments rather than kept separately.

If you would rather audition imports before they join the rest of the library, say so — having them land in their own sub-folder is a small change to make.

A quick check that an import came out right: load the instrument, open the **INFO** tab, and look at **Zones** and **Format**. That page reports what is actually in the bundle on disk.
